

Abstract

A screening device includes a screen and frame, and is useful in permitting fishermen to detect conditions of the water to be fished for optimum bait and lure selection. The screening device allows a fisherman to collect aquatic insects rising through the water to be fished, thus alerting the fisherman as to the food being seen and eaten by the fish, and identify what depth the insects are in the water. With this knowledge, the fisherman can select the proper lure or fly to catch the fish present in the tested waters.
